

# Crystal Binding

- Kittel Chapter 3
- Simon (oxford Solid state Basics)

# What holds a crystal together?

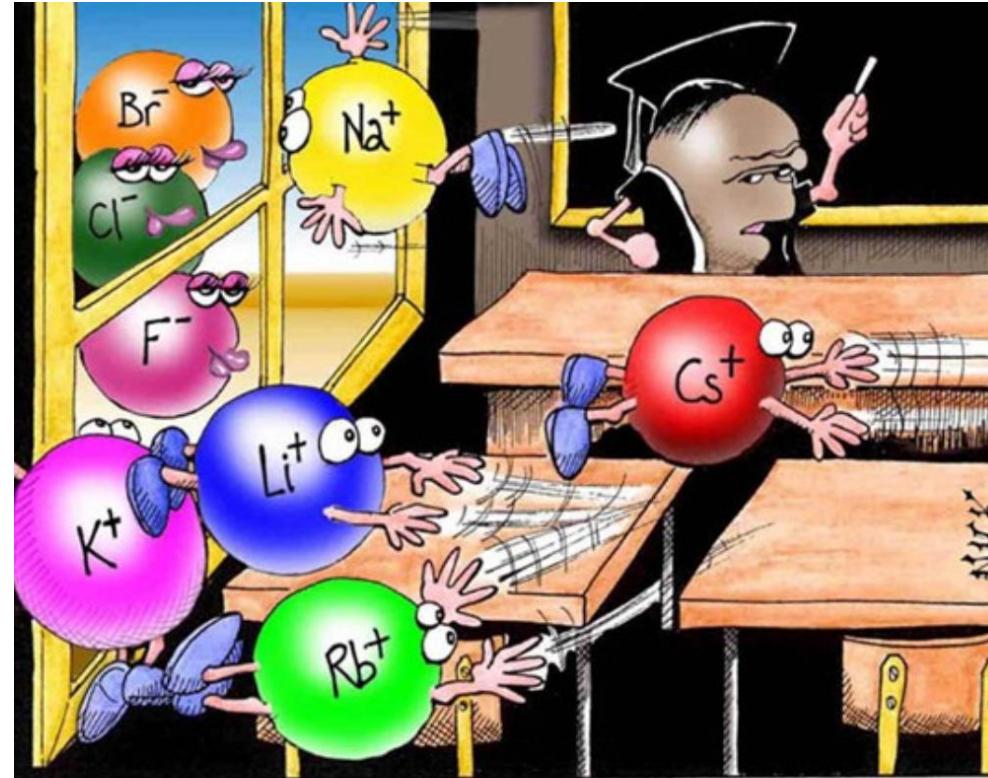

mainly,

electrostatic interaction

(also: dipole fluctuations)

(gravitational and magnetic  
forces: negligible)

Goal : energy minimization

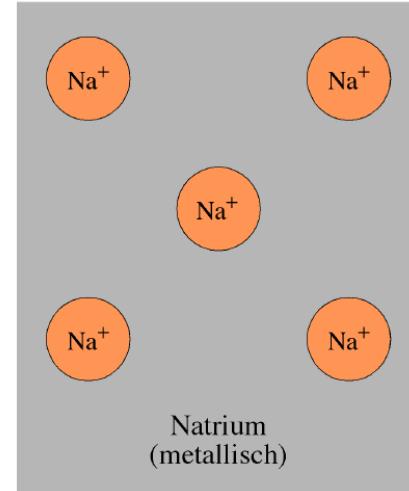

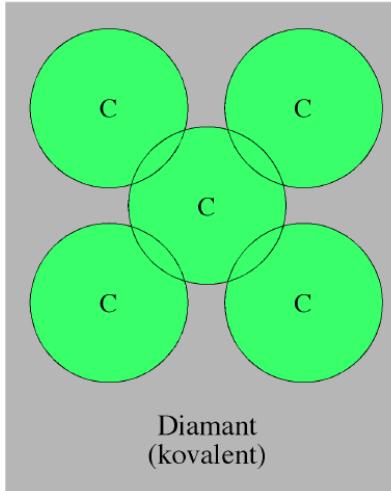

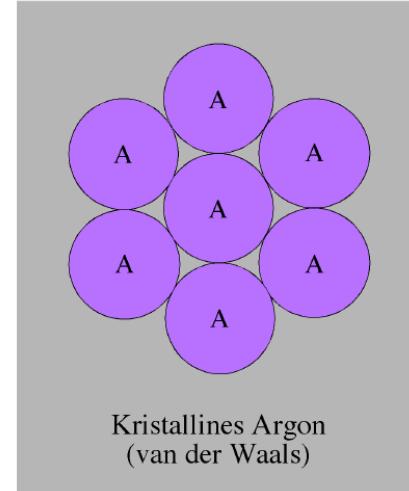

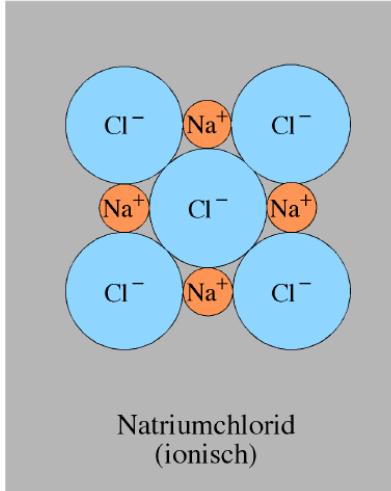

*"Perhaps one of you gentlemen would mind telling me just what it is outside the window that you find so attractive..?"*

Cartoon courtesy of NearingZero.net

# Basic types of binding

Crystals are classified with respect to their binding type

- Van der Waals
- Ionic
- Covalent
- Metal
- Hydrogen

## Van der Waals interaction

typical between inert atoms (He, Ne, Kr...) and between inert molecules (i.e. N<sub>2</sub>)

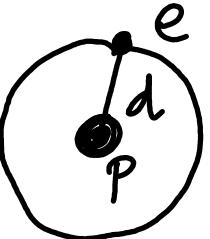

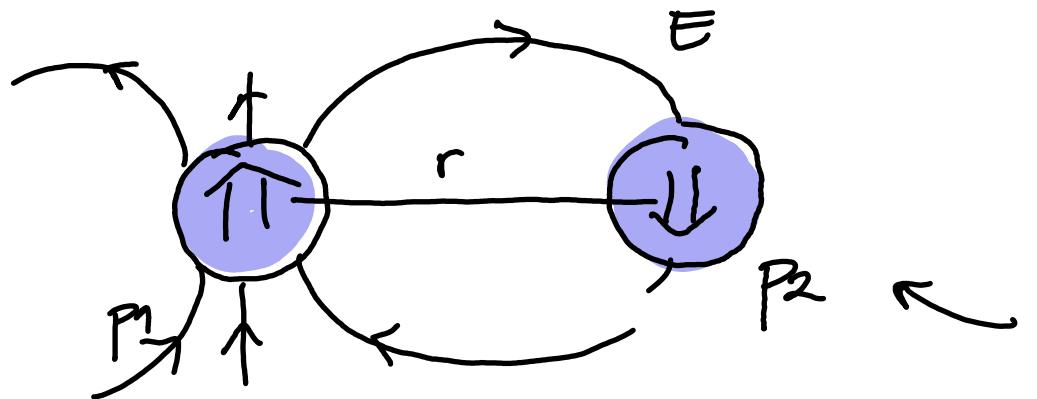

Noble (inert) gases : electron distribution in the crystalline state = free atom

- all electronic shells are completely filled
- spherically symmetric charge distributions
- closed packed structures (fcc) [except He]
- ionization energy is high
- weakly bounded : interaction between induced dipoles  
→ van der Waals interaction

(recap previous class)

# Van der Waals interaction

Atom 1 & 2 separated  $r$ :

- dipole moment  $\vec{p} = e \cdot \vec{d}$
- in general,  $e^-$  "orbits"  $\rightarrow \langle p \rangle = 0$
- if  $\vec{E}$  is applied to the atom  
 $\Rightarrow \vec{p} = \chi \vec{E}$

$\chi$  electric susceptibility

If we have 2 of these atoms separated  $r$ :

- if atom 1 has for a moment a dipole  $p_1$
- then atom 2 feels  $E = \frac{p_1}{4\pi\epsilon_0 r^3}$
- so, atom 2 develops  $p_2 = \chi E$

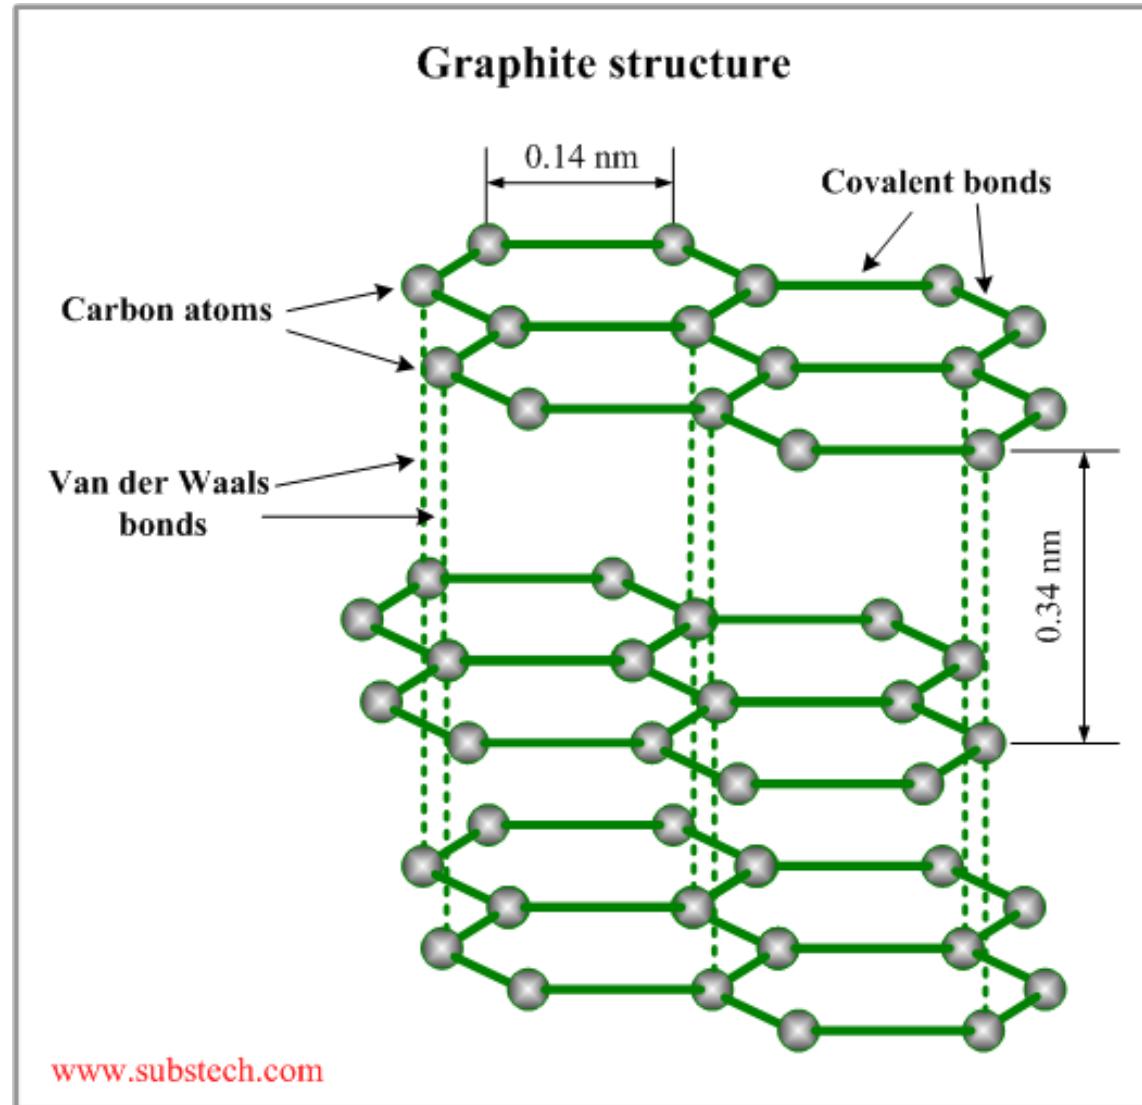

Potential energy between 2 dipoles:

$$U = -\frac{|p_1||p_2|}{4\pi\epsilon_0 r^3} = -\frac{|p_1|\chi E}{4\pi\epsilon_0 r^3} = -\frac{|p_1|^2 \chi}{(4\pi\epsilon_0 r^3)^2}$$

$$U = -\frac{A}{r^6}$$

Always attractive!

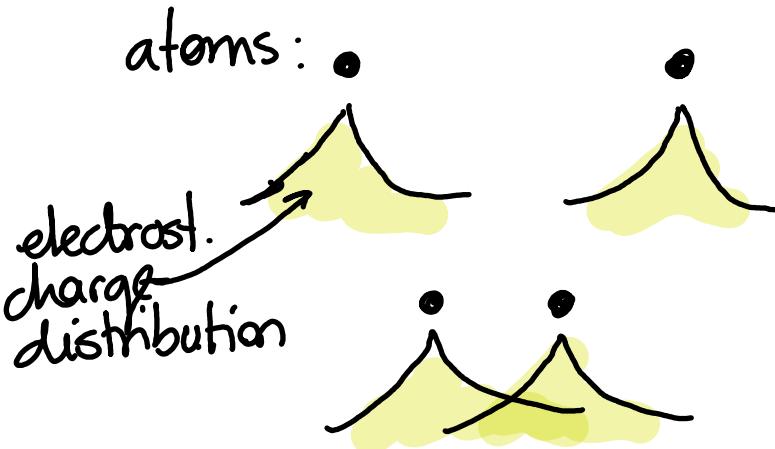

# Van der Waals bonds

## Van der Waals bonds used Gecko's

# Repulsive interaction

as 2 atoms approach  $\Rightarrow$  potential energy  $\uparrow$   
due to Pauli exclusion princ.  
 $\Rightarrow$  repulsive interaction

Phenomenologically,

$$U_{\text{rep}}(r) \propto \frac{B}{r^{12}}$$

$$B > 0$$

$$U_{\text{rep}} \sim \lambda e^{-r/\rho}$$

$$\lambda > 0$$

or, equivalently,

$\lambda, \rho, B$  are empirically determined  
(from fitting data on inert gases)

# Lennard-Jones potential

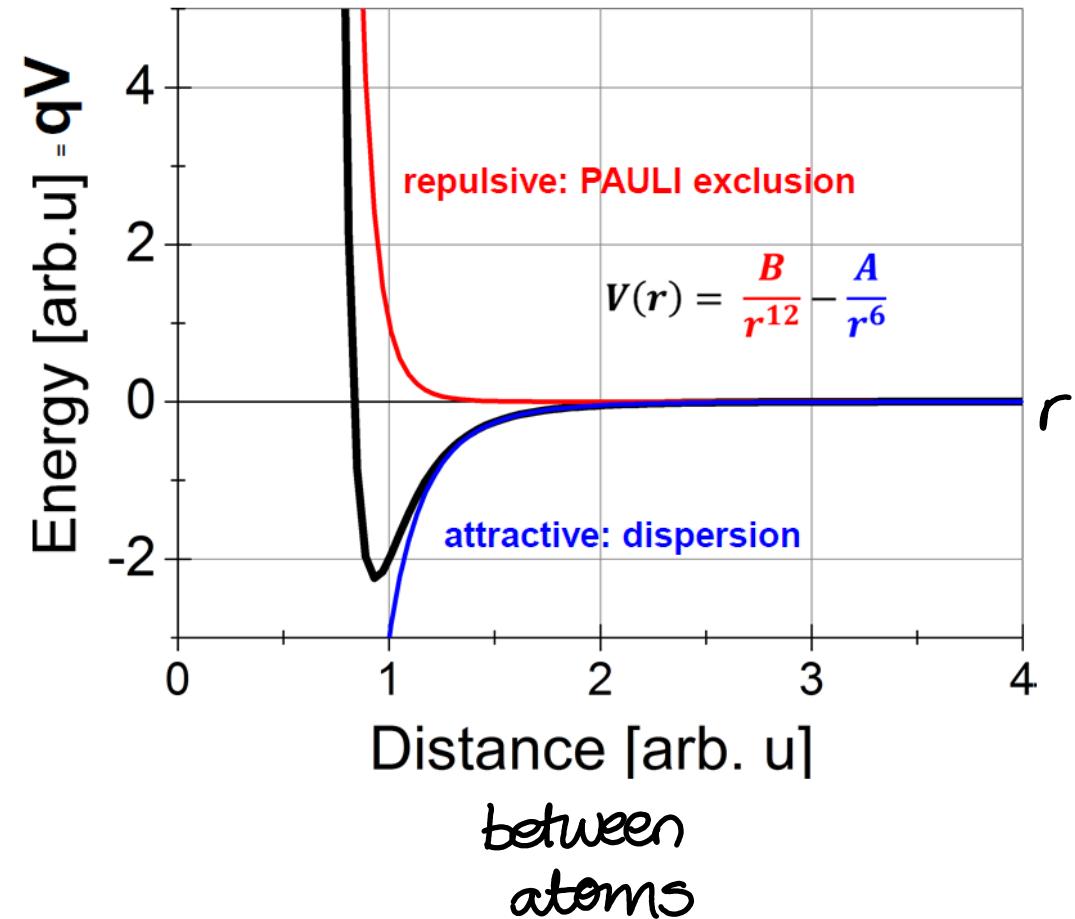

between two atoms:

$$U(R) = \frac{B}{R^{12}} - \frac{A}{R^6} \equiv 4\epsilon \left[ \left(\frac{\sigma}{R}\right)^{12} - \left(\frac{\sigma}{R}\right)^6 \right]$$

where  $A \equiv 4\pi\sigma^6$  and  $B \equiv 4\pi\sigma^{12}$

Pauli Repulsion

attractive interact.  
(van der Waals)

# Equilibrium lattice constants

$$u(R) = 4\epsilon \left( \left(\frac{\sigma}{R}\right)^{12} - \left(\frac{\sigma}{R}\right)^6 \right)$$

$$U_{TOT} = 4\epsilon \sum_{i=1}^N \sum_{\substack{j=1 \\ j \neq i}}^N \left[ \left(\frac{\sigma}{R_{ij}}\right)^{12} - \left(\frac{\sigma}{R_{ij}}\right)^6 \right] \times \frac{1}{2}$$

↑  
correction  
factor to avoid double counting

being  $R_{ij}$  = distance between atoms

let's define  $R_{ij} = p_{ij} R$  where  $R$  = distance between nearest neighbours  
 $\rightarrow p_{ij} \geq 1$

$$U_{TOT} = 4N\epsilon \left( \left(\frac{\sigma}{R}\right)^{12} \sum_{j \neq i}^N \frac{1}{p_{ij}^{12}} - \left(\frac{\sigma}{R}\right)^6 \sum_{i \neq j}^N \frac{1}{p_{ij}^6} \right)$$

↑  
fixing  $i$  and  
introducing factor  $N$

$\underbrace{\hspace{1cm}}$  fcc : 12.1318...       $\underbrace{\hspace{1cm}}$  fcc : 14.45392

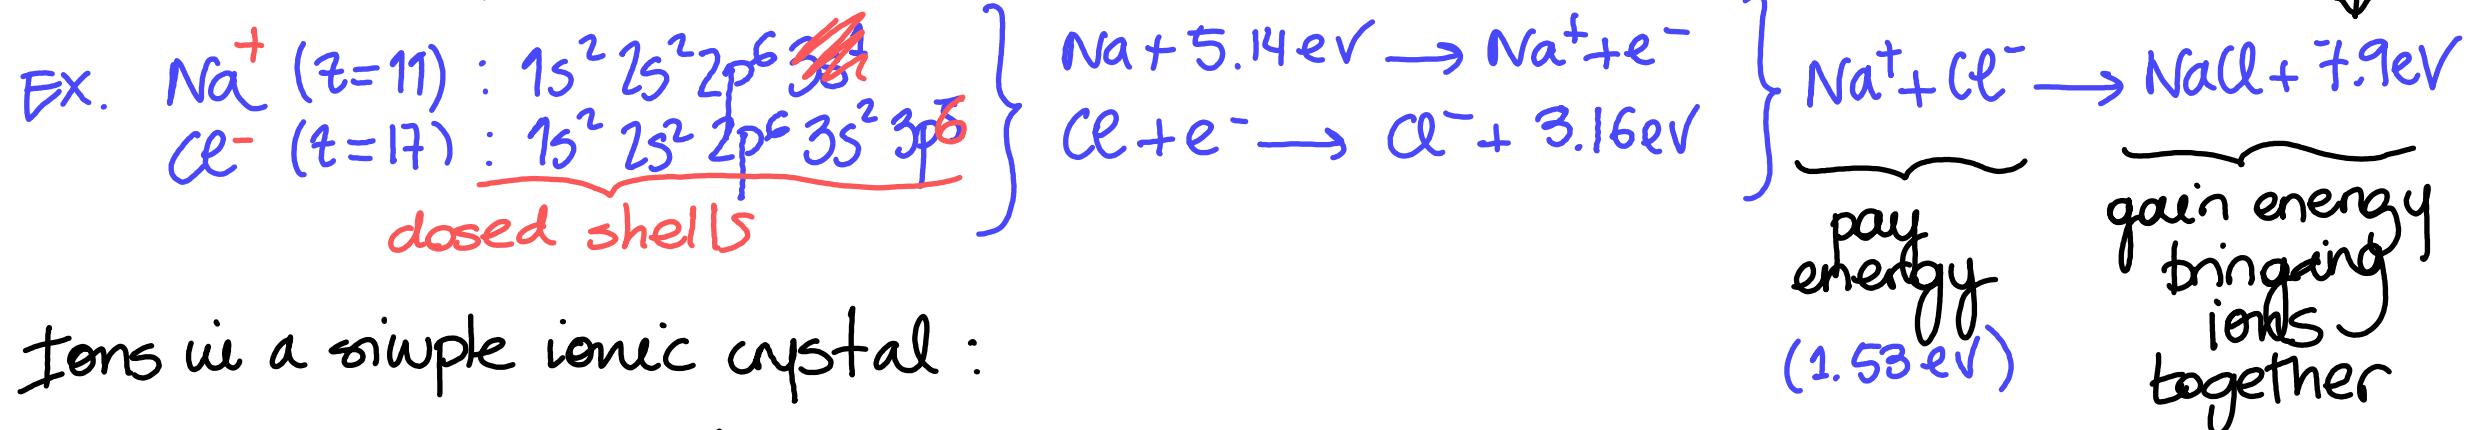

Equilibrium distance :

$$\frac{dU}{dR} = 0 \Rightarrow R_0$$

Cohesive energy :  $U(R_0)$

# Ionic bonding

Idea: For some compounds, it is energetically favourable to physically transfer one  $e^-$  from one atom to the other

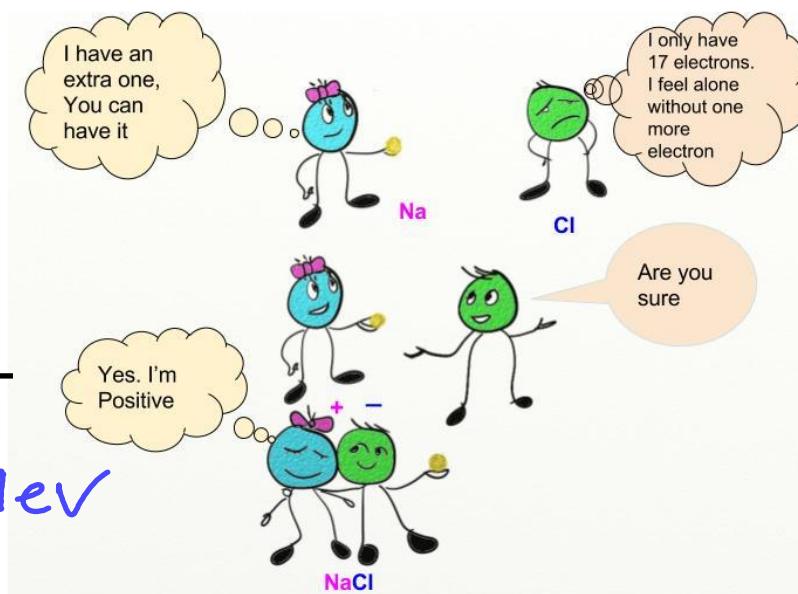

Ions in a simple ionic crystal :

- Electronic configuration: closed shells
- spherical charge distributions
- Low ionization energies

► Coulomb interaction provides most of the Lattice Energy.

$\text{NaCl}$  (FCC,  $a = 5.62 \text{ \AA}$ )

$$U_{\text{lattice measured}} = 7.9 \text{ eV}; U_{\text{Coulomb}} = \frac{1}{4\pi\epsilon_0} \frac{e^2}{a/2} \approx 5.1 \text{ eV}$$

By comparing having  $1e^-$  at  $\infty$  or on the atom,

**Ionization energy:** Energy required to remove one electron from a neutral atom to create a positive ion

$$E_i = E(\text{Na}^+ + e^-) - E(\text{Na}) > 0$$

**Electron affinity:** Energy gain from creating a negative ion from a neutral atom by adding an electron

$$E_{af} = E(\text{Cl}^- + e^-) - E(\text{Cl}) < 0$$

$$\begin{array}{c} \rightarrow E_{af} \uparrow \\ \rightarrow E_i \uparrow \end{array}$$

Mulliken

✓ Electronegativity =  $\frac{\text{Electron affinity} + \text{Ionsization Energy}}{2}$

! there are many different definitions

In a bond, the  $e^-$  is always transferred from the atom with the lower to the one with the higher electronegativity

# Madelung energy (Electrostatics)

$\frac{N}{2}$  "molecules" with 2 atoms of charge  $\pm q$

$$U = N \sum_{\substack{i=j \\ \text{ions}}} \underbrace{\left( \lambda e^{-\frac{r_{ij}}{\rho}} \pm \frac{q^2}{4\pi\epsilon_0 r_{ij}} \right)}_{\substack{\text{Pauli} \\ \text{Coulomb}}} \times \frac{1}{2} \quad \text{correction}$$

\* note: van der Waals is very small in ionic crystals!

- define  $r_{ij} = p_{ij} R$  ( $R$  = nearest neighbours distance)

- consider repulsive interaction for only first neighbours:  $\lambda e^{-\frac{R_{ij}}{\rho}} \approx \lambda z e^{-\frac{R}{\rho}}$

then,

$$U_{TOT} = \frac{N}{2} \left( z \lambda e^{-\frac{R}{\rho}} - \frac{q^2}{4\pi\epsilon_0 R} \sum_{i \neq j}^N \pm \frac{1}{p_{ij}} \right)$$

$$\boxed{\alpha = \sum_{i \neq j}^N \pm \frac{1}{p_{ij}} = \text{MADELUNG CONSTANT}}$$

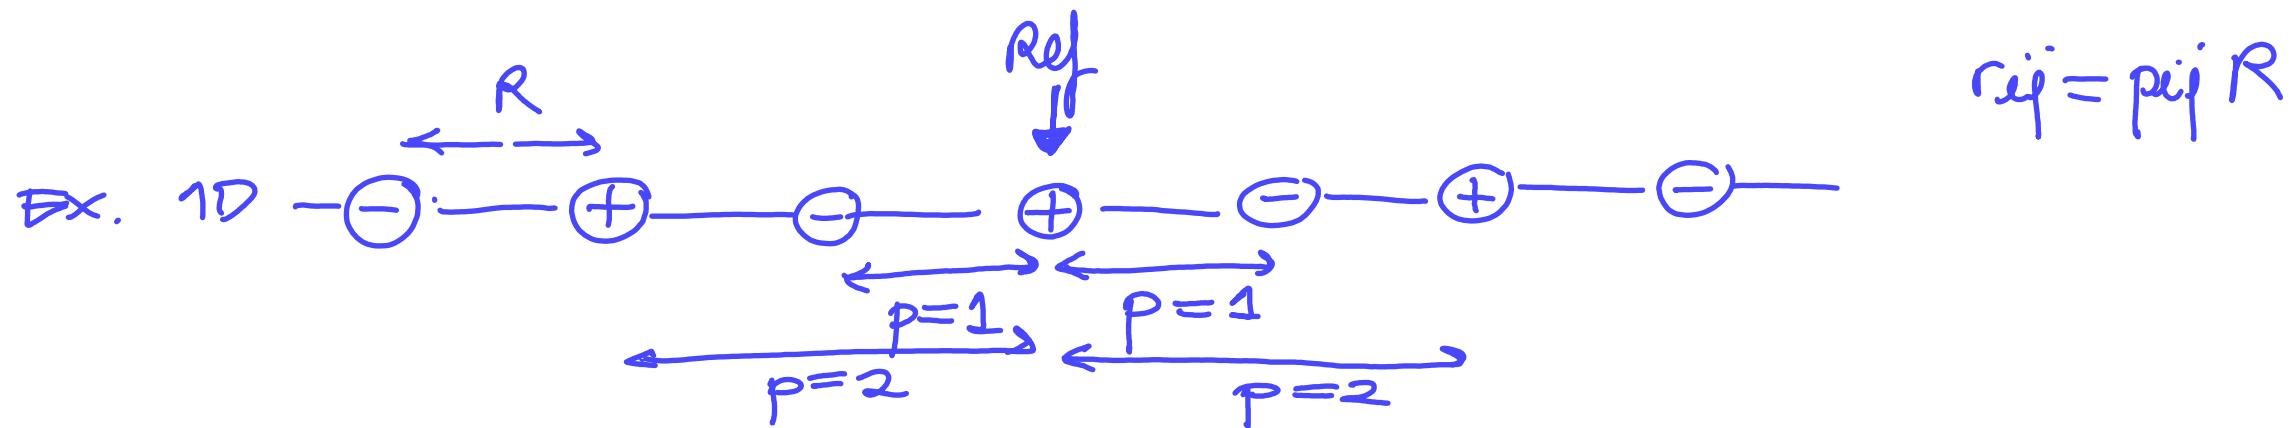

parameter  
 $\downarrow$   
 $\uparrow$   
 number of  
 first  
 neigh.

## Modeling constant

$$\alpha = \sum_{i \neq j}^N \pm \frac{1}{P_{ij}}$$

it depends on the structure

it must be positive to ensure stability

$$\alpha = \sum_{i \neq j}^N \pm \frac{1}{P_{ij}} = 2 \cdot \left( 1 - \frac{1}{2} + \frac{1}{3} - \dots \right) = 2 \ln 2 = 1.38629$$

## Bonding in KCl

Some properties of ionic solids:

- Hard materials (due to Coulomb int between + & - ions)
- High melting T
- in qd., insulators (because charges are strongly bounded to ions)

However, water (which is very polar) can dissolve them

From  $U_{\text{TOT}}$ , the equilibrium distance  $R_0$ :  $\frac{dU}{dR} = 0$

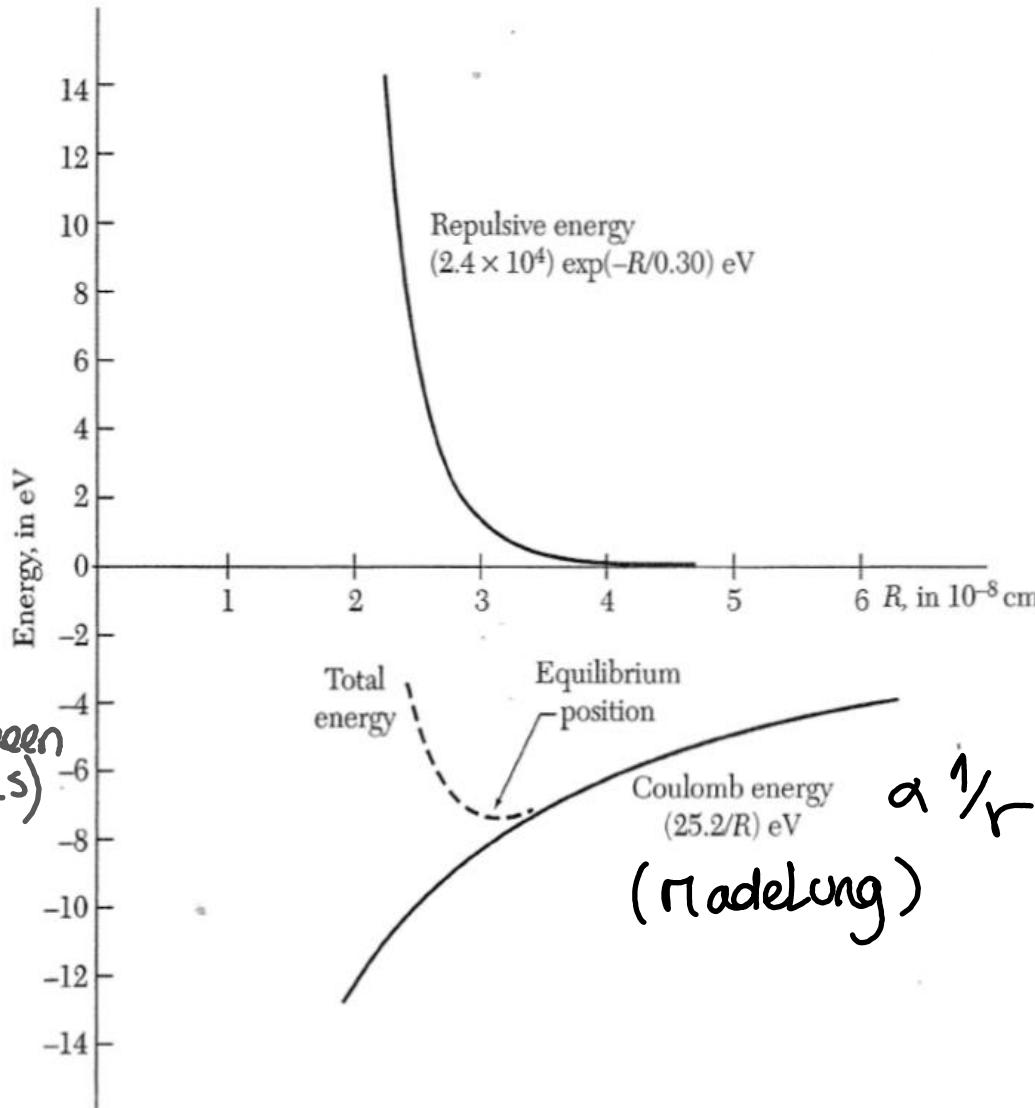

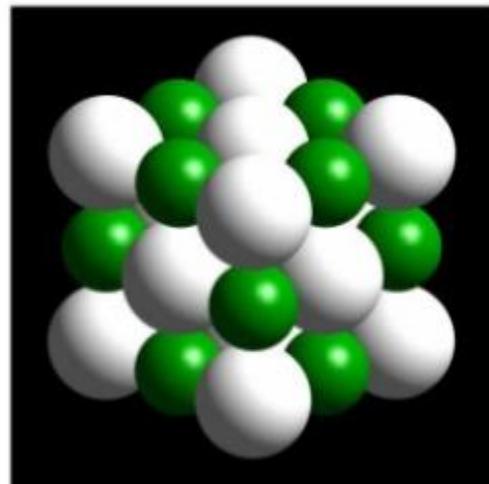

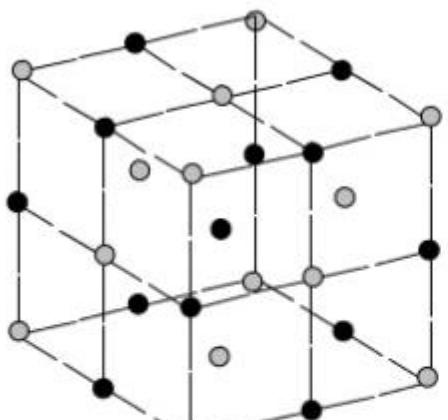

Figure 10 Energy per molecule of KCl crystal, showing Madelung (coulomb) and repulsive contributions.

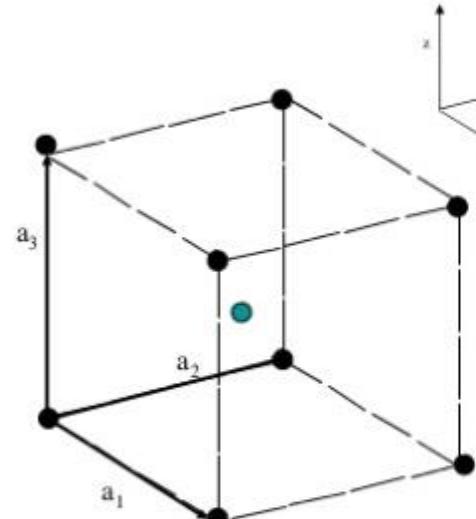

## NaCl Structure

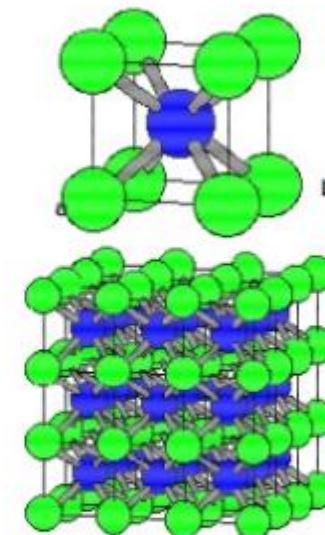

Face Centered Cubic Bravais Lattice

Favored for ionic crystals with large size difference  
Close packed negative ions with small positive ions

## CsCl Structure

Simple Cubic Bravais Lattice

From <http://www.ilpi.com/inorganic/structures/cscl/index.html>

Favored for ionic crystals with small size difference

## Covalent bonds

Si, Ge, diamond : very important bond type!

Idea: electrons are roughly shared between two atoms

- strong bonding
- directional bonding
- brittle
- electrons are preferentially located between atoms
- antiparallel alignment of spins

in gl, insulators or semiconductors

Sarah, I'm cold.

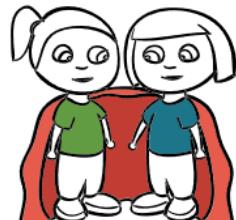

Emily

I'm cold too

Sarah

Emily and Sarah  
→ share the blanket

Emily Sarah

Wow, we both feel so cozy and comfortable after sharing the blanket.

# Covalent bond

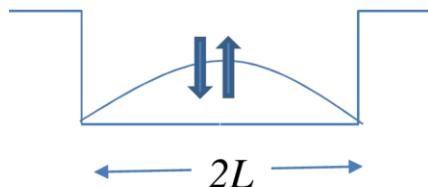

"Particle in a box picture"

i.e. atom in a box with 1e<sup>-</sup> (i.e. hydrogen atom)

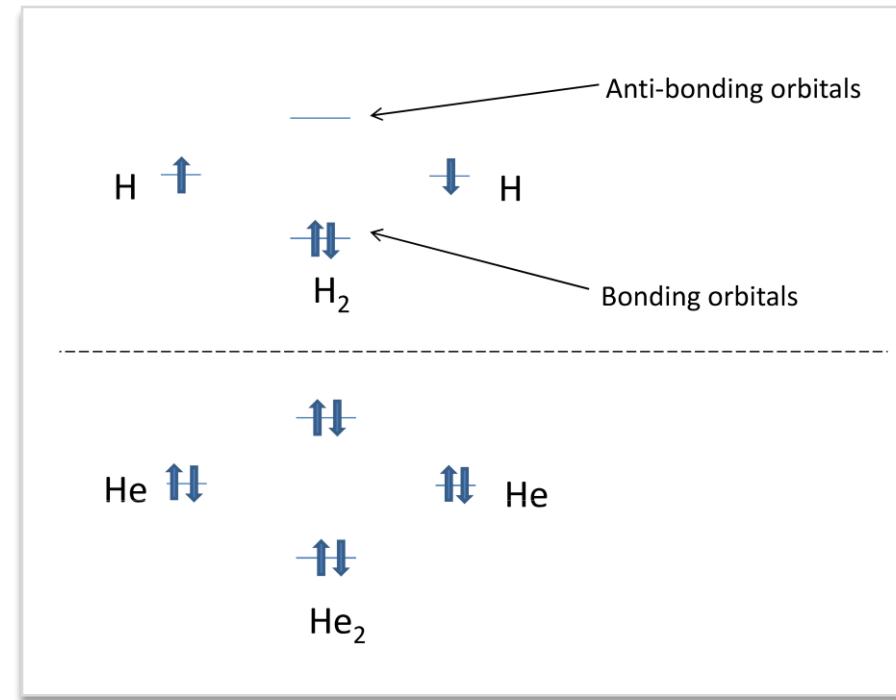

$$E = \frac{\hbar^2 \pi^2}{2mL^2}$$

$$E = \frac{\hbar^2 \pi^2}{2m(2L)^2}$$

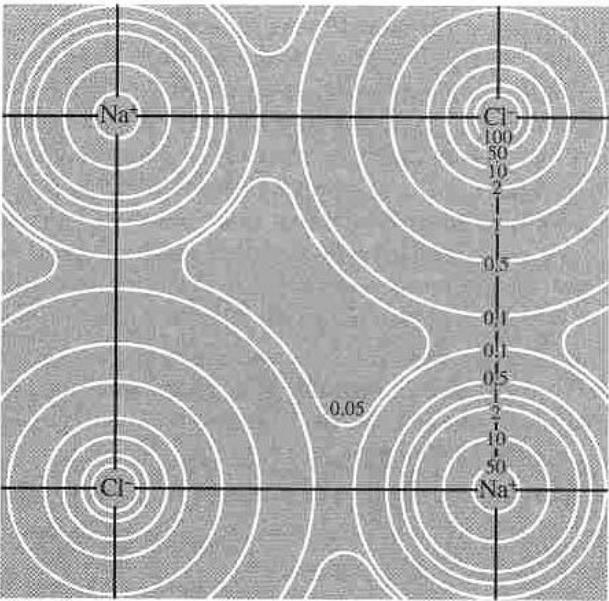

e<sup>-</sup> shared between 2 atoms  
can delocalize and lower  
the energy

He: 2e<sup>-</sup> per atom  
⇒ bonding & antibonding filled  
⇒ Total energy not reduced  
⇒  $He_2$  does not form

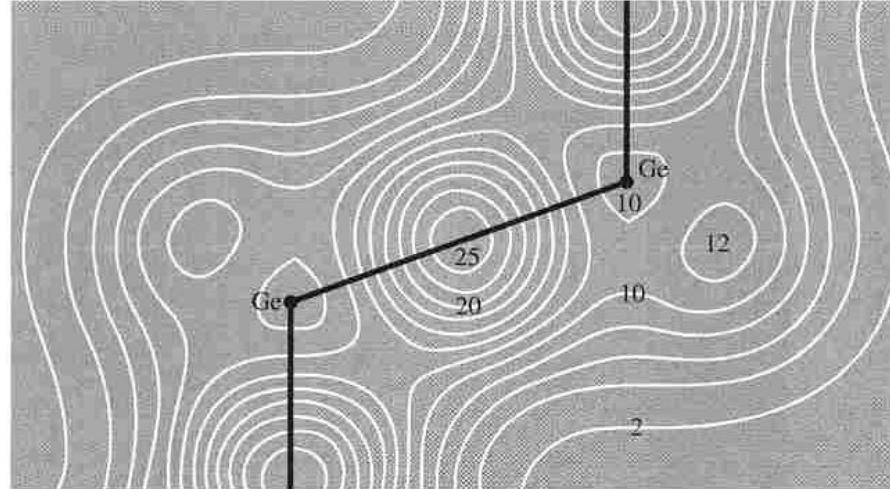

# Electron density distribution

Ionic

Electron density contribution in the base plane of  $\text{NaCl}$ , after x-ray measurements

Covalent

Calculated valence electron concentration in Germanium

! there is a continuous range of crystals between covalent and ionic limit!

# Metallic bonding

The periodic table is color-coded to highlight elements based on their electronic properties:

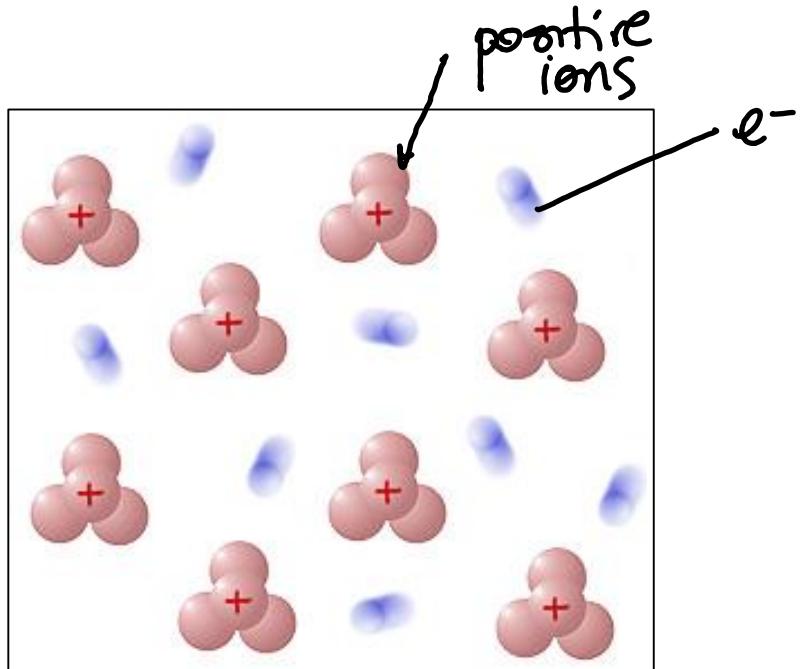

- Metal:** Shown in blue.
- Metalloid:** Shown in green.
- Nonmetal:** Shown in yellow/gold.

Specific elements highlighted in blue include Boron (B), Carbon (C), Nitrogen (N), Oxygen (O), Phosphorus (P), Sulfur (S), Chlorine (Cl), Bromine (Br), Iodine (I), and Xenon (Xe). These are typically considered post-transition metals or metalloids.

# Metallic bonding

Idea: "positive ions embedded in an electron sea"

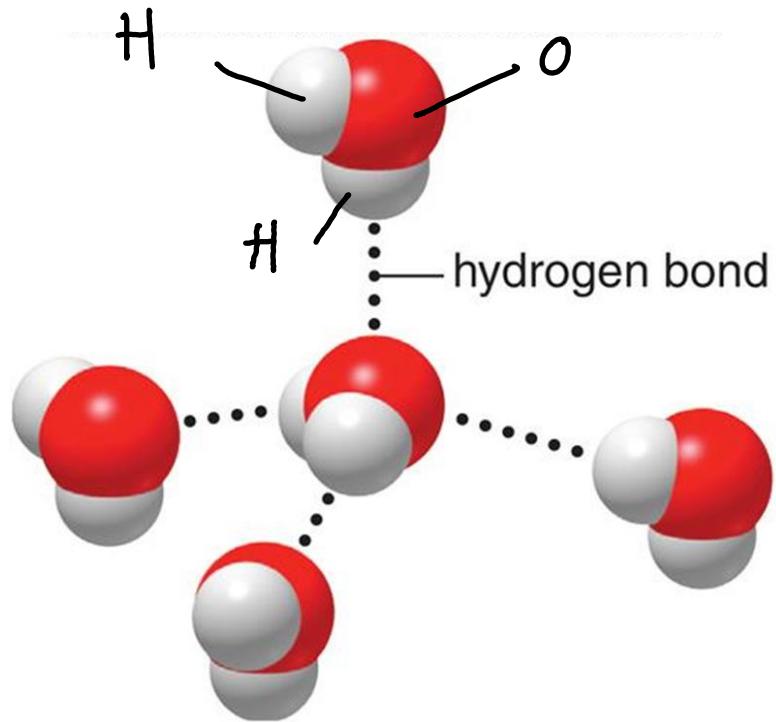

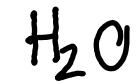

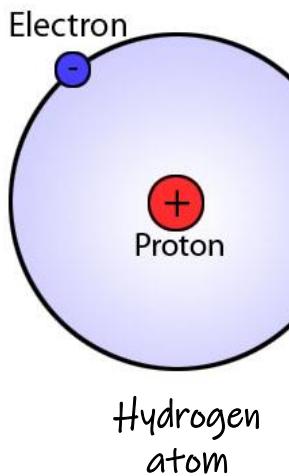

## Basic properties of metals

- Excellent electric conductivities
- " thermal "
- Relatively more ductile than covalent bond

typical structures : fcc, hcp, bcc

# Hydrogen bonds

Very important in biology too; i.e. they hold together strands of DNA

# Types of Bonds in Solids

Type of Bonding	Description	Typical of which compounds	Typical Properties
Ionic	Electron is transferred from one atom to another, and the resulting ions attract each other	Binary compounds made of constituents with very different electronegativity: Ex, group I-VII compounds such as NaCl.	<ul style="list-style-type: none"> <li>• Hard, Very Brittle</li> <li>• High Melting Temperature</li> <li>• Electrical Insulator</li> <li>• Water Soluble</li> </ul>
Covalent	Electron is shared equally between two atoms forming a bond. Energy lowered by delocalization of wavefunction	Compounds made of constituents with similar electronegativities (ex, III-V compounds such as GaAs), or solids made of one element only such as diamond (C)	<ul style="list-style-type: none"> <li>• Very Hard (Brittle)</li> <li>• High Melting Temperature</li> <li>• Electrical Insulators or Semiconductors</li> </ul>
Metallic Bonds	Electrons delocalized throughout the solid forming a glue between positive ions.	Metals. Left and Middle of Periodic Table.	<ul style="list-style-type: none"> <li>• Ductile, Maleable (due to non-directional nature of bond. Can be hardened by preventing dislocation motion with impurities)</li> <li>• Lower Melting Temperature</li> <li>• Good electrical and thermal conductors.</li> </ul>
Molecular (van der Waals or Fluctuating Dipole)	No transfer of electrons. Dipole moments on constituents align to cause attraction. Bonding strength increases with size of molecule or polarity of constituent.	Noble Gas Solids, Solids made of Non-Polar (or slightly polar) Molecules Binding to Each Other (Wax)	<ul style="list-style-type: none"> <li>• Soft, Weak</li> <li>• Low Melting Temperature</li> <li>• Electrical Insulators</li> </ul>
Hydrogen	Involves Hydrogen ion bound to one atom but still attracted to another. Special case because H is so small.	Important in organic and biological materials	<ul style="list-style-type: none"> <li>• Weak Bond (stronger than VdW though)</li> <li>• Important for maintaining shape of DNA and proteins</li> </ul>

# A summary about forces

interaction type	range	directional	energy [kJ / mol]	energy [k <sub>B</sub> T]
charge – charge	$\sim r^{-1}$	no	100 - 900	40 - 360
metal bond		no	100 - 900	40 – 360
covalent	very short	yes	100 - 900	40 - 360
hydrogen bond	very short	yes	10 - 155	4 - 62
dipole – dipole	$\sim r^{-3}$	yes	20	8
van der Waals	$\sim r^{-6}$	weakly	0,5 - 5	0,2 - 2

van der Waals bonds can sum up energies, and for large objects the van der Waals forces can even become long range forces

## Learning outcomes – Crystal Binding

- Be familiar with the characteristics of the different type of bondings:
  - van der Waals
  - Ionic
  - Covalent
  - Metallic
  - Hydogen
